Comenzamos con la maquina de W7

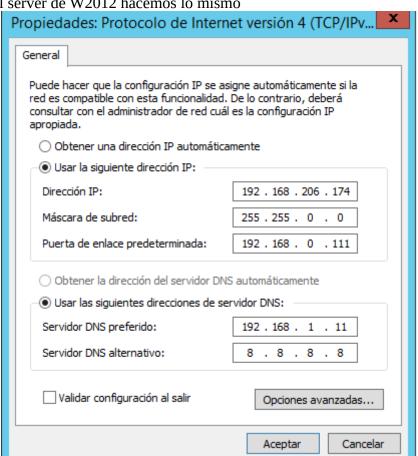

Entramos en las propiedades del Prtocolo de Internet version 4 y las ajustamos a nuestra ip asociada en clase

Comprobamos en el cmd con un ping

En la maquina del server de W2012 hacemos lo mismo

En la de ubuntu neceistamos usar estos comandos mostrados en las capturas, en la primera cambiaremos la ip y la mascara

```
TX packets 104 bytes 8340 (8.3 KB)

TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

root@ubuntuserver20:/home/alumno# sudo ifconfid enp0s3 192.168.206.171 netmask 255.255.0.0
```

En esta cambiaremos el DNS

```
# This file is managed by man:systemd-resolved(8). Do not edit.

# This is a dynamic resolv.conf file for connecting local clients to the

# internal DNS stub resolver of systemd-resolved. This file lists all

# configured search domains.

# Run "resolvectl status" to see details about the uplink DNS servers

# currently in use.

# Third party programs must not access this file directly, but only through the

# symlink at /etc/resolv.conf. To manage man:resolv.conf(5) in a different way,

# replace this symlink by a static file or a different symlink.

# See man:systemd-resolved.service(8) for details about the supported modes of

# operation for /etc/resolv.conf.

nameserver 8.8.8.8_

options edns0 trust-ad
```

Le cambiamos el nombre a la maquina

```
GNU nano 4.8 /etc/hostname
ServidorLinux04
```

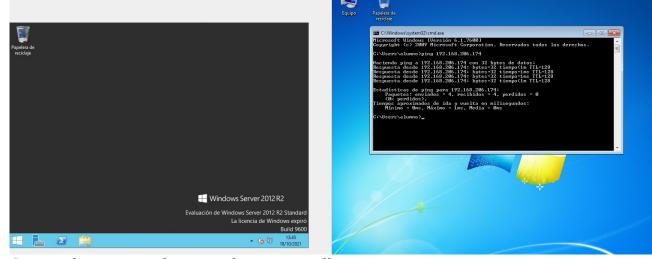

Por lo cual para asociar el nombre a la IP de bucle interno tendremos que cambiarlo tambíen

```
GNU nano 4.8

127.0.0.1 localhost
127.0.1.1 ServidorLinux04

# The following lines are desirable for IPv6 capable hosts
::1 ip6-localhost ip6-loopback
fe00::0 ip6-localnet
ff00::0 ip6-mcastprefix
ff02::1 ip6-allnodes
ff02::2 ip6-allrouters
```

Despues de desactivar el firewall vamos a comprobar si desde una maquina podemos ver otra

Como podemos comprobar se pueden ver entre ellas
